

Quiz #2 of Computer Networks

Christian Rinderknecht

3 April 2007

1. Suppose that we have a circuit-switched network where

- users share a 1 Mbps link;
- each user alternates periods of activity and of inactivity:
 - when he is active, he generates data at the constant rate of 100 Kbps;
 - when he is idle, he produces no data.
- each user is active during 10% of the time.

Question: How many users can the link support?

2. Consider a message of size $7.5 \cdot 10^6$ bits, three links of rate 1.5 Mbps connecting two hosts (i.e., there are two switches in-between them) and assume that there is no congestion and no delay at the switches.

Question: How much time is required to send and receive the message?

3. The situation is as in case 2 but now the message is broken into two packets of equal size.

Question: Assuming that only one packet can travel a link at a time, how much time is required to send and receive the message?
